LIFE INSURANCE, FINANCIAL DEVELOPMENT AND ECONOMIC GROWTH IN SOUTH AFRICA

Athenia Bongani Sibindi*

Abstract

The life insurance sector may contribute to economic growth by its very mechanism of savings mobilisation and thereby performing an intermediation role in the economy. This ensures that capital is provided to deficient units who are in need of capital to finance their working capital requirements and invest in technology thereby resulting in an increase in output. In this way, it could be argued that life insurance development spurs financial development. In this article we investigate the causal relationship between the life insurance sector, financial development and economic growth in South Africa for the period 1990 to 2012. We make use of life insurance density as the proxy for life insurance development, real per capita growth domestic product as the proxy for economic growth and real broad money per capita as the proxy for financial development. We test for cointegration amongst the variables by applying the Johansen procedure and then proceed to test for Granger causality based on the vector error correction model (VECM). Our results confirm the existence of at least one cointegrating relationship amongst the variables. The results indicate that the direction of causality runs from the economy to the life insurance sector which is consistent with the “demand-following” insurance-growth hypothesis. There is also evidence of causality running from the economy to financial development which is consistent with the “demand following” finance-growth hypothesis.

The results also reveal that life insurance complements economic growth in bringing about financial development further lending credence to the “complementarity” hypothesis.

1. Introduction

The relationship between the life insurance sector, financial development and economic growth is an intriguing one and continues to preoccupy the minds of scholars in the field. Hitherto the finance-growth nexus research has largely focused on either the banking sector or the stock market. Scant research has been conducted to unravel the relationship between the life insurance sector, financial development and the real sector. It is imperative to highlight that the life insurance sector plays a critical role to any economy by its very mechanism of promoting savings by way of life policies, and hence fostering intermediation. Moreover its ability to pool funds in the form of premiums enables it to be an important institutional investor. Such funds can be used to buy equity of other firms, which capital will be used by such companies to buy equipment, plant or other technological innovations, resulting in those companies realising economies of scale and hence increased output. The life insurance sector also increases liquidity in the market as investors who are involved in the securitisation of home loans. Thus they bear the risk and hence allow banks to advance more loans to the population at large. This results in more credit being extended and hence will impact on financial development.

The present study aims to contribute to the finance-growth nexus literature by specifically focusing on the life insurance sector in the context of South Africa. Hitherto the studies that have been conducted focusing on South Africa have largely been of a cross-sectional or panel nature (See for example Han, Li, Moshirian et al, 2010 and Azman-Saini and Smith, 2011). The major disadvantage of panel data methods of analysis is that the country specific effects could be ignored or at worst lost altogether in the analysis. As such it is essential to also interrogate the relationship between life insurance, financial development and economic growth by conducting time series studies based on South Africa. The motivation in selecting South Africa as the focus of this study lies in its stage of
development and the sophistication of its financial sector notwithstanding that it is a developing country.

The impetus behind this study is also to establish the nature of the relationship between the life insurance sector, financial development and economic growth in South Africa in light of the findings by Ward and Zurbruegg (2000) which are later corroborated by Chang, Lee and Chang (2013) to the effect that the insurance-growth nexus varies from country to country. To the best of our knowledge there has been no in-depth study that has focused on South Africa. It is equally compelling that Ward and Zurbruegg (2000) suspect that cultural, regulatory, legal environment and the improvement in financial intermediation amongst other factors may confound the insurance-growth relationship. It could be argued that South Africa presents itself as the best case study as it has a very diverse culture, its financial system has improved vastly over the years and attendant to this the regulatory environment has also evolved over the years.

We thus also hope to chart the way forward for policy makers in South Africa as they grapple with policies that are aimed at recovering her economy and securing the financial sector, specifically targeted at the insurance sector. To this end there has been a raft of reforms that have been proposed. Amongst others, these include the Solvency Assessment Management (SAM) regime whose main aim is to improve the capital and solvency levels of insurance companies as well as the Treating Customers Fairly (TCF) regulations which are aimed at protecting the insurance consumers. We intend to investigate the causal relationship between life insurance, financial development and economic growth by first testing for cointegration amongst the variables for a long run relationship by applying the Johansen procedure. We will then estimate a Vector Error Correction Model (VECM). Lastly we will then conduct Granger Causality/Block Exogeneity tests based on the vector error correction model to determine the nature and direction of flow of causality amongst the variables.

The remainder of paper is arranged as follows: the next section reviews the literature about the insurance-growth nexus. Section 3 reviews the empirical literature. Section 4 gives an overview of the life insurance sector in South Africa. Section 5 describes the data, methodology and presents the empirical results. Section 6 discusses economic and policy implications and then Section 7 concludes.

2. Review of Literature: Insurance and Growth Nexus

The finance-economic growth nexus theory has evolved over the years and can be traced to the works of Schumpeter (1912) and later McKinnon (1973). The main argument by Schumpeter was the important role played by financial institutions in spurring technological innovation and economic activities. The financial activities of savings mobilisation, project evaluation, risk monitoring and management facilitate these two functions. On the other hand McKinnon posits that financial development is spurred by restrictive government regulations, interest rate ceilings, loan subsidies and high reserve requirements for the banking sector.

It would seem that there is consensus amongst the scholars when characterising the finance-growth nexus as follows: (1) there is no causal relationship; (2) the causal relationship is demand-following, that is, economic growth leads to a demand in financial services; (3) the causal relationship is supply-leading, that is growth in the financial sector will spur economic growth; (4) negative causal relationship from finance to growth; (5) interdependence.

Hitherto extant studies have interrogated the finance-growth nexus by mainly focusing on the stock markets and the banking sector. There is scant research that focuses on the insurance sector. The importance of the insurance sector in economic development continues to seize the attention of scholars and has gained prominence over the last two decades. Amongst the early scholars who interrogated this relationship include Ward and Zurbruegg (2000). They aver that insurance is important to economic development mainly because of the following two reasons: (1) the benefits that accrue as a result of the insurance company being an agent of risk transfer and indemnification and (2) the benefits that accrue as a result of the insurer undertaking activities as a financial intermediary. Using a sample of nine OECD countries they come to the conclusion that the causal relationships between economic growth and insurance market development may well vary across countries. Further they contend that the influence of insurance market development while channelled through indemnification and financial intermediation is tempered by country specific factors.

Haiss and Sümegi (2008) are in concordance with Ward and Zurbruegg (2000) and contend that the insurance sector is important to economic growth as it can be used as a channel of risk transfer, saving and investment. In their study of 29 European countries they found out that the aggregate investment by insurance companies grew by 20% relative to gross domestic product (GDP) within the time span of 1993-2004. They go on to observe that an essential part of the contribution of insurance companies to GDP growth derives from their assets, their investment activities and the companies’ setup. Thus the participation by insurance companies in the economy results in the expansion of the investment horizon, increase of market volume and improvement of market efficiency.

The latter strand of literature emphasises the investment, innovation and financial development that is spurred by the growth of the insurance sector. According to the proponents of this view, insurance companies by providing protection could affect
economic growth through the channels of marginal productivity of capital, technological innovations and saving rate (Ćurak, Lončar and Poposki, 2009). Thus insurance companies indemnify the ones who suffer a loss and stabilise the financial position of individuals and firms. They go on further to note that the possibility of transfer of risks to insurance companies induces risk adverse units to buy goods and services especially those of higher values. In this way insurance sustains demand or consumption of goods and services which encourage production, employment and finally economic growth. Ćurak, Lončar and Poposki (2009) also propound that insurance companies increase the availability of funds through their innovative products which provides protection from credit risk to other financial intermediaries. In that way financial intermediaries become more willing to lend funds for financing real investments that encourage economic growth. They also contend that insurance could affect economic growth through the saving rate channel by offering various life insurance products that combine risk protection and saving benefits. Further they argue that insurers lower transaction costs or achieve economies of scale by collecting funds from dispersed economic units who pay relatively small premiums and by allocating these amassed funds to deficit economic units in order to finance large projects.

According to Azman-Saini and Smith (2011) insurance companies as financial intermediation agents create another dimension of competition in the market for intermediated saving which is expected to promote productive efficiency. Furthermore improved financial intermediation services allow investors to hold diversified investment portfolios, which facilitate a willingness to invest in risky high-productivity projects. Moreover, insurance markets boost liquidity which facilitates a flow of funds to capital-accumulating projects, resulting in the expansion of the economy. They posit that insurance may also have an indirect impact on output growth via its potential impact on the development of banks and stock markets. They contend that, for example, the provision of protection services to customers against risks that might otherwise leave them unable to repay their debts may promote bank lending.

In sum the relationship between the life insurance sector, financial development and the real sector could be classified in terms of causality with respect to six possible null hypotheses:

$H_1$: Life insurance sector development causes economic growth

$H_2$: Life insurance sector development causes financial development

$H_3$: Financial development causes life insurance sector growth

$H_4$: Financial development causes economic growth

3. Review of the Empirical Literature

Ward and Zurbruegg (2000) examined the relationship between economic growth and growth in the insurance industry for nine OECD countries. Using annual data they conducted a bivariate cointegration analysis and also tested for causality by regressing the real GDP against the total real premiums in each country from 1961 to 1996. They found out that in some countries the insurance industry Granger causes economic growth, and in other countries economic growth Granger causes the insurance sector development.

Haiss and Sümegi (2008) investigated the impact of insurance investment and premiums on GDP growth in Europe. They conducted a cross-country panel data analysis for 29 European countries for the period 2005 to 2009. The insurance indicators that they used are the gross premium income as a total sum of life and non-life premium income and total investments. They separated the aggregate sample into a group of mature market economies (mainly the “old” EU-15) and the other one consisting of former transition economies mainly the new EU member states from Central and Eastern Europe (CEE). Their results showed evidence for a correlation between insurance investments and GDP growth for EU-15 countries with mature financial markets and a short-run connection between non-life expenditure and GDP for the emerging market-type CEE countries.

Arena (2008) examined the causal relationship between the insurance market activity and economic growth in both developed and developing countries. He employed insurance penetration (insurance premiums as a percentage of GDP) as a proxy for insurance market development. By using generalised method of moments (GMM) for dynamic models of panel data for 55 countries between 1976 and 2004, he found a robust evidence for this relationship. He found that both life and non-life insurance have a positive and significant causal effect on economic growth.

Ćurak, Lončar and Poposki (2009) using an endogenous growth model and panel data estimation techniques examined whether life and non-life insurance individually or collectively contribute to economic growth across a sample of 10 transition European member countries for the period 1992 to 2007. The proxy that they used for insurance development is insurance penetration. Their results indicated that insurance sector development positively and significantly promotes economic growth. The results were confirmed in terms of life, non-life insurance as well as total insurance.
Han, Li, Moshirian, et al (2010) investigated the relationship between insurance development and economic growth by employing generalised method of moments (GMM) models on a dynamic panel data set of 27 economies for the period 1994-2005. They used insurance density (premiums per capita) as a proxy for the insurance sector development. They found fairly strong evidence in favour of the hypothesis that insurance development contributes to economic growth. They find out that for the developing countries the overall insurance development, life insurance and non-life insurance development play a much important role than they do for the developed economies.

Ching, Kogid and Furuoka (2010) examined the existence of a causal relationship between the life insurance sector and economic growth in Malaysia by applying the Johansen cointegration test and the Granger causality test based on the Vector Error Correction Model (VECM). They used the total assets of the life insurance sector as an indicator for life insurance. They found out that there existed more than one cointegrating relationship between the real GDP and the total assets of life insurance sector. The study further showed that the real GDP of Malaysia was Granger caused by the total assets of Malaysian life insurance sector in the short run.

Azman-Saini and Smith (2011) investigated the impact of insurance sector development on output growth, capital accumulation and productivity improvement using data from 51 countries (both developing and developed) for the period 1981-2005. They employed the life insurance penetration ratio as a proxy for the development of insurance markets. Making use of panel data methods of analysis they find evidence that insurance sector development affects growth predominantly through productivity improvement in developed countries, while in developing countries it promotes capital accumulation.

Islam (2012) utilised the error correction mechanism to test the causal relationship between the development of non-bank financial intermediaries (NBFI) and economic growth in Malaysia over the period 1974-2004. He used the financial assets as the proxy for NBFI development. He then conducted Granger causality tests based on the vector error correction mechanism (VECM) and found out that there is a unique long-run causality running from nonbank financial intermediaries to economic growth.

Horng, Chang and Wu (2012) tested for a dynamic relationship amongst insurance demand, financial development and economic growth in Taiwan between 1961 and 2006. They used a three variable Vector Autoregressive (VAR model) with insurance density (premiums per capita) utilised as the proxy for insurance demand. They found out that in the short run, economic growth Granger causes insurance demand and financial development Granger causes economic growth. These results supported the ‘supply-leading theory’ link from financial development to economic growth and the ‘demand-following theory’ link from economic growth to insurance demand.

Chi-Wei, Hsu-Ling and Guochen (2013) applied the bootstrap Granger causality test to examine the relationship between insurance development and economic growth in 7 Middle Eastern countries. They used insurance density as the indicator for insurance development. They found evidence for bi-directional causality between the life insurance sector and economic growth in the higher income countries such as United Arab Emirates, Kuwait and Israel. They also found that economic growth Granger causes non-life insurance development in the low income countries of Oman, Jordan and Saudi Arabia.

Chang, Lee and Chang (2013) studied the relationship between insurance and economic growth by conducting a bootstrap panel Granger causality test using data from 10 OECD countries over the period of 1979-2006. They employed the life insurance, non-life insurance premiums and total insurance premiums as the proxies for insurance market activities. Their results were mixed and they found evidence of one-way Granger causality running from insurance activities to GDP in 5 out of OECD countries, namely France, Japan, Netherlands, Switzerland and the UK. Thus insurance is of great importance for economic growth in these countries. Secondly they found evidence of one-way Granger causality running from GDP to insurance activities in Canada (for life insurance activity), Italy (for total and life insurance activities) and the US (for total and non-life insurance activities). This result indicated that economic growth can increase demand of insurance and thus lead to the development of insurance markets. Thirdly they found out that in the US, there was two-way Granger causality (feedback) between life insurance activity and GDP lending credence to both the “supply-leading” and “demand-following” hypotheses. This result suggested that in the US the life insurance market and economic growth are both endogenous indicating that they mutually influence each other. Finally they found no causal relationship between insurance activities and GDP in Belgium (for all insurance activities), Canada (for total and non-life insurance activities), Italy (for non-life insurance activity) and Sweden (for life insurance activity). These results were consistent with the “neutrality hypothesis” for the insurance-growth nexus. This implied that insurance development and economic growth may not influence each other in those sectors and in Belgium.

4. An Overview of the Life Insurance Sector in South Africa

The insurance sector in South Africa comprises of 79 long-term insurers and 7 long-term reinsurers, (FSB, 2012). In South Africa the insurance companies that
transact life insurance business are referred to as long-term insurers.

The key metrics of the insurance companies for the period 2011 to 2013 are given in Tables 1 and 2. The gross premiums of long-term insurance companies show a remarkable growth of 43% from about R301 billion registered in 2011 to roughly R430 billion registered in 2013. A similar trend is observed when evaluating the total assets with the long-term insurance industry registering a phenomenon growth in total assets of 32% from roughly R1, 7 trillion in 2011 to R2, 3 trillion in 2013.

The information provided in Table 2 depicts the investment vehicles of the insurance companies. It would seem that for the long-term insurers the top three investment vehicles in order of importance are: equities and collective investment schemes, debentures and loan stock and cash and deposits. Thus it would seem that the long-term insurance companies play a critical role in intermediation, savings and resource mobilisation.

5. Data and Methodology

5.1 Measures of Life Insurance and Financial Development

In this paper we make use of insurance density as a proxy to gauge the level of insurance sector development in South Africa. Insurance density is defined as premiums per capita, measured by quarterly premium payments divided by the population. This follows the procedure adopted by Han, Li, Moshirian, et al, 2010 and Horng, Chang and Wu, 2012 amongst other. In our model we make use of quarterly data. We employ the real gross domestic product (RGDP) per capita as a proxy for economic growth, long-term insurance density (LFID), as a proxy for life insurance development and real broad money per capita (YM2) as the proxy for financial development. The quarterly, gross domestic product, real broad money and insurance premium data for the years 1990 to 2012 were obtained from the South Africa Reserve Bank (SARB) database. The national population figures were extracted from the International Financial Statistics (IFS) database. A GDP deflator was applied on the nominal values to calculate the real values, with the year 2000 being set as the base year.

The trends in life insurance development, financial development and economic growth are shown in Figure 1. The gross domestic product per capita (RGDP) shows an upward trend, though it takes a dip between 1991 and 1992. It then peaks at around R9000 at the end of 2008 then declines in 2009 before it ultimately recovers. This is explicable as it corresponds to the period of financial crises. Long-term insurance density (LFID) shows a much steeper sustained upward growth from levels around R560 per capita in 1990 to a peak of around R1400 per capita in 2007. It would then decline to about R820 per capita in 2009 before it recovered to levels around R1020 per capita in 2012. Broad money supply per-capita also exhibits a similar trend starting from a high of R13500 per capita in 1990, it will initially decline to the lowest level of around R10780 in 1994. It would then increase to a pick level of around R24260 per capita at the end of 2008 before it declines to a low level of R20 870 in 2010 before it eventually recovers to levels around R21760 in 2012.
Thus it is evident that the series exhibit some form of co-movement and hence we suspect that they are cointegrated in the long run.

**Figure 1.** Trends of life insurance development indicators in South Africa during the period 1990 to 2012.

### 5.2 Empirical model specification and estimation techniques

In order to investigate the relationship between life insurance, financial development and economic growth, we make use of the Granger causality test. The Granger causality test is based on the vector error correction model between life insurance, financial development and economic growth.

A vector error correction (VEC) model is a restricted VAR designed for use with non-stationary series that are known to be cointegrated. The VEC has cointegration relations built into the specification so that it restricts the long run behaviour of the endogenous variables to converge to their cointegrating relationships while allowing for short-run adjustment dynamics. We test for Granger causality based on the error correction model which can be expressed as follows:

\[
\Delta \text{rgdp} = a_0 + \sum_{i=1}^{n} a_1 \text{rgdp}_{t-i} + \sum_{i=1}^{n} a_2 \Delta \text{lfid}_{t-i} + \sum_{i=1}^{n} a_3 \Delta \text{ym2}_{t-i} + a_4 \text{ECT}_{t-1} + \mu_t
\]  

\[
\Delta \text{lfid} = b_0 + \sum_{i=1}^{n} b_1 \text{lfid}_{t-i} + \sum_{i=1}^{n} b_2 \Delta \text{rgdp}_{t-i} + \sum_{i=1}^{n} b_3 \Delta \text{ym2}_{t-i} + b_4 \text{ECT}_{t-1} + \varphi_t
\]  

\[
\Delta \text{ym2} = c_0 + \sum_{i=1}^{n} c_1 \Delta \text{ym2}_{t-i} + \sum_{i=1}^{n} c_2 \Delta \text{rgdp}_{t-i} + \sum_{i=1}^{n} c_3 \Delta \text{lfid}_{t-i} + c_4 \text{ECT}_{t-1} + \psi_t
\]
5.2.1 Stationarity tests

The variables were subjected to stationarity tests. These were the Phillips-Perron and Augmented Dickey Fuller tests. The results of the stationarity tests are presented in Table 3. All variables were found to be non-stationary when tested at their levels. They became stationary when differenced once. As such it can be concluded that the variables are integrated and of order one.

5.2.2 Cointegration analysis

Thus having established that all the variables are non-stationary and integrated of order one, we proceed and test for the number of cointegrating relationships by applying the Johansen Test for Cointegration. Cointegrated variables ensure that we eliminate spurious relations and as such share common stochastic trends. Further than that, they enable us to formulate an error correction model as we determine the long-run relationship among the variables. We first estimate an unrestricted VAR and determine the lag length selection criteria. The optimum lag length selected is 5 (Refer to Table 4). We thus then apply the Johansen test using the optimum lag length of 5. The results as presented in Table 5 suggest that there is one cointegrating relationship among the variables. The null hypothesis that there is no cointegrating vector is rejected as the trace statistic is greater than the critical value from the Johansen table. We conclude therefore that there is one cointegrating vector.

5.2.3 Granger causality

Having established that there is at least one cointegrating relationship between the economic growth, financial development and life insurance variables, we proceed to perform Granger Causality/Block Exogeneity Wald tests for causality based on the error correction model. The results are reported in Table 6. The results show that there is no causal flow from life insurance to economic growth. We fail to reject the null hypothesis of exogeneity of the life insurance variable in the economic growth function at the 10% level of significance as the p-value (0.6878) is greater than 0.10. We also fail to reject the exogeneity of the financial development variable in the economic growth function as the p-value (0.1729) is greater than 0.10.

However when the dependent variable is long-term insurance density, we reject the null hypothesis of the exogeneity of economic growth variable at the 5% level of significance as the p-value (0.0135) is less than 0.05. However the financial development variable is exogenous in the long-term insurance function as its p-value (0.8337) is insignificant. When the dependent variable is financial development, we reject the null hypothesis of exogeneity and find that both the economic growth and long-term insurance variables are endogenous as their p-values of 0.0000 and 0.0921 are highly significant at the 1% and 10% level of significance respectively. These results imply that economic growth Granger causes long-term insurance development. Thus the direction of causality runs from economic growth to long-term insurance development without feedback. Further economic growth Granger causes financial development without feedback. There is also evidence to suggest unidirectional Granger causality running from life insurance to financial development.

Our results thus support the following null hypotheses that we set out to probe:

\( H_2: \) Life insurance sector development causes financial development
\( H_3: \) Economic growth causes life insurance sector development
\( H_4: \) Economic growth causes financial development.

6. Economic and Policy Implications

Our empirical results suggest that life insurance, financial development and economic growth are cointegrated, that is they move in tandem to each other in the long run. We also wish to highlight key findings and proffer policy advice. Firstly, we find evidence of one-way Granger causality running from economic growth to the life insurance sector in South Africa. This is consistent with the “demand following” insurance-growth hypothesis. We also find evidence of one way Granger causality running from economic growth to financial development in South Africa. This is also consistent with the “demand following” hypothesis. There is also evidence of one way Granger causality running from life insurance to financial development. As such it would seem that life insurance “complements” economic growth in bringing about financial development. The policy implication is that the policy makers must put in place policies that will grow the South African economy. With the growth of the South African economy an enhanced demand for life insurance products will be created and hence leading to the development of the insurance sector. Further the growth of the life insurance sector through its savings mechanism will result in an increase of...
intermediation and hence stimulating financial development.

**7. Conclusion**

This paper examines the causal relationship between life insurance, financial development and economic growth in South Africa as understanding the link is critical to policy makers in their quest to grow the economy and regulate the financial services sector. We find evidence that the economic growth spurs the development of the long-term insurance sector as well as influences financial development in South Africa. Our findings lend credence to ‘demand-following’ insurance-growth hypothesis. Further this is also consonant with our *a priori* expectations, that for developing countries, the demand-following hypothesis subsists. Our empirical findings also lend credence to the “complementarity” hypothesis. Thus, it would seem economic growth and life insurance variables complement each other, rather than substitute one another in bringing about financial deepening and financial development. As the insurance-growth nexus will continue to preoccupy the minds of researchers, we also suggest that in the future the focus of this research should also turn to the interplay of culture, regulation and the influence of other financial intermediaries. It could also be telling to explore the use of other proxies for life insurance sector development such as total assets, or the insurance penetration ratio or a composite thereof.
