Abstract

This paper empirically examines the causal relation between financial development and economic growth in the case of Jordan for the period 1965 to 2004. That is, the paper attempts to provide answers to the following questions: a) Does financial development promotes economic growth? Or b) Does economic growth promotes financial development? Using Toda and Yamamoto (1995) Granger-no-causality model, the results reveal that there is a unidirectional Granger causality from economic growth to financial development (as defined by log (DC/GDP)).

Keywords: Financial Development, Economic Growth, Granger non-Causality, MENA, Jordan

1. INTRODUCTION

The relationship between financial development and economic growth has been investigated extensively in the literature. This investigation of such a relationship has been initiated by Schumpeter (1911) and followed by more recent work of McKinnon (1973) and Shaw (1973). Literature shows that two hypotheses are used to explain the direction of causality between financial development and economic growth. First, the supply-leading hypothesis that supports the argument that financial development promotes economic growth (see, for example, Levine and Zervos (1998), McKinnon (1993), and Shaw (1973)). Second, the demand-following hypothesis which supports the argument that economic growth promotes financial development (see, for example, Robinson (1962) and Stiglitz (1994)).

2. DATA AND METHODOLOGY

To investigate the causal link between financial development and economic growth in the case of Jordan, the paper will use annual data for the period 1965-2004 on real gross domestic product (RGDP), and two proxies for financial development: the ratio of broad money (M2) to GDP (M2/GDP) and the ratio of domestic credits to the private sector (DC) to GDP (DC/GDP). Data on real GDP are extracted from Groningen Growth and Development Center (2006) and data on both (M2/GDP) and (DC/GDP) are extracted from the World Bank, World Development Indicators.

The methodology used in this study follows Toda and Yamamoto (1995) procedure in order to test the Granger causality between economic growth and financial development. As an advantage of this method, Toda and Yamamoto (1995) stated that “Our method is applicable whether the VAR’s may be stationery (around a deterministic trend), integrated of arbitrary order, or cointegrated of an arbitrary order. Consequently, one can test linear or nonlinear restrictions on the coefficients by estimating a levels VAR and applying the Wald criterion, paying little attention to the integration and cointegration properties of the time series data in hand (Toda and Yamamoto, 1995, p.227)". This procedure involves two steps. First, to determine the lag length (k) of the VAR model and augment that with the maximum order of integration (dmax) of the variables used in the model. We used Schwarz criterion (SC) to determine the optimal lag structure (k) of the VAR model. We also used the Augmented Dickey-Fuller (ADF) test to determine the order of integration (dmax) of the variables used in the model. Second, to test for Granger causality by using the Modified Wald (MWALD) test in order to test the coefficients of the first k coefficients of the VAR (k+dmax). That is, Zapata and Rambaldi (1997) stated that “Toda and Yamamoto (1995) prove that the Wald test for restrictions on the parameters of a VAR (k) has an asymptotic Chi-square distribution when a VAR (k+dmax) is estimated where dmax is the maximal order of integration suspected to occur in the process (Zapata and Rambaldi, 1997, p. 291)". In addition, Zapata and Rambaldi (1997) argued that the MWALD test does not requires initial knowledge.
of cointegration and or the degree of integration of the system.

Here, let \( Y_t \) represents economic growth (measured by real GDP) and \( FD_t \) represents financial development (measured by two proxies: \( X \) and \( M \) being log (DC/GDP) and log (M2/GDP), respectively).

\[
Y_t = \alpha_1 + \sum_{i=1}^{k_{max}} \alpha_{2i} Y_{t-i} + \sum_{i=0}^{k_{max}} \alpha_{3i} FD_{t-i} + \epsilon_t \quad (1)
\]

\[
FD_t = \beta_1 + \sum_{i=1}^{k_{max}} \beta_{2i} Y_{t-i} + \sum_{i=0}^{k_{max}} \beta_{3i} FD_{t-i} + \epsilon_t \quad (2)
\]

Rambaldi and Doran (1996) have explained that the MWald test used for testing Granger non-causality can be more efficient when using a Seemingly Unrelated Regression (SUR) method. Thus, based on Toda and Yamamoto (1995) procedure, the Granger non-causality between economic growth and financial development can be tested using the following VAR system given in equations (1-2).

For example, when using Toda and Yamamoto (1995) approach to test the Granger non-causality from FD to \( Y_t \), we need to test the null hypothesis: \( \alpha_{3i} = 0 \) for all \( i \leq k \) in equation 1 and causality from FD to \( Y_t \) can be established through rejecting the null hypothesis stated above. A similar procedure can be used to test the causality from \( Y_t \) to FD, i.e., to test \( H_0: \beta_{3i} = 0 \) for all \( i \leq k \) in equation 2 and causality from \( Y_t \) to FD can be established if \( \beta_{3i} \neq 0 \) for all \( i \leq k \).

### 3. EMPIRICAL RESULTS

Following Toda and Yamamoto (1995) method, before testing for the non-causality between economic growth and financial development, we need to establish the lag length (\( k \)) of the VAR model and the order of integration (\( d_{max} \)) of the variables used in the model. We used the Schwarz Information Criterion (SC) to establish the lag length (\( k \)) of the VAR model. According to the SC, the optimal lag length (\( k \)) for the VAR was established at 1, i.e. \( k=1 \). For the order of integration (\( d_{max} \)) of the variables used, the ADF test was used. The ADF results given in Table 1 show that all the variables are integrated of order one (i.e., \( I(1) \)).

#### Table 1. ADF Unit Root Test (The null hypothesis: \( Y, X, \) and \( M \) have a unit root)

<table>
<thead>
<tr>
<th>Country/Period</th>
<th>Variables</th>
<th>Level</th>
<th>First Difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jordan (1965-2004)</td>
<td>( Y )</td>
<td>(-2.643) (2)</td>
<td>(-2.897^{*}) (2)</td>
</tr>
<tr>
<td></td>
<td>( X )</td>
<td>(-1.643) (0)</td>
<td>(-7.023^{***}) (0)</td>
</tr>
<tr>
<td></td>
<td>( M )</td>
<td>(-2.507) (0)</td>
<td>(-5.252^{***}) (0)</td>
</tr>
</tbody>
</table>

Notes: \( Y, X, \) and \( M \) as defined above. Optimal lags according to Schwarz Information Criterion (SIC) are given in parentheses. ***, **, and * indicate significance levels of the 1%, 5%, and 10%, respectively.

Table 2 reports Chi-square statistics and the p-values for the purpose of testing the Granger-no-causality. The results show that the null hypothesis of Granger-no-causality from financial development to economic growth cannot be rejected. The results also show that the null hypothesis of Granger-no-causality from economic growth to financial development (defined as log(M2/GDP)) cannot be rejected. However, the null hypothesis of Granger-no-causality from economic growth to financial development (defined as log(DC/GDP)) is rejected lending support to one-way Granger causality form economic growth to financial development.

#### Table 2. Granger Causality Test Results Based on Toda-Yamamoto Method

<table>
<thead>
<tr>
<th>Ho</th>
<th>Lag Length/Var order</th>
<th>MWald Statistics(d.o.f.)</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>X does not cause ( Y )</td>
<td>1/2</td>
<td>2.61 (1)</td>
<td>0.1064</td>
</tr>
<tr>
<td>Y does not cause ( X )</td>
<td>1/2</td>
<td>3.42 (1)</td>
<td>0.0645*</td>
</tr>
<tr>
<td>M does not cause ( Y )</td>
<td>1/2</td>
<td>0.53 (1)</td>
<td>0.4685</td>
</tr>
<tr>
<td>Y does not cause ( M )</td>
<td>1/2</td>
<td>0.51 (1)</td>
<td>0.4735</td>
</tr>
</tbody>
</table>

Notes: \( Y, X, \) and \( M \) as defined above. Optimal lags are determined according to Schwarz Information Criterion (SIC). Degrees of freedom are given in parentheses. ***, **, and * indicate rejection of the null hypothesis at significance levels of the 1%, 5%, and 10%, respectively.

### CONCLUSION

This study empirically examines the causality relationship between financial development and economic growth in Jordan using the Granger-no-causality method developed by Toda and Yamamoto (1995). The empirical results give no support to the hypothesis that financial development causes (in the Granger sense) economic growth. It was economic growth that Granger causes financial development.

The results support the demand-following hypothesis for Jordan. This suggests that reforms in the financial sector may not lead to promoting economic growth. The results should, however, be interpreted with caution due to omission of some variables. It should also be noted that the results may be sensitive to the choice of the measures that are used as proxies for financial development.
